#### Outline

- PART O: The problem
- PART 1: RDF: The lingua franca for information exchange
  - Why
    - 1. Focus on semantics
    - 2. Easier data integration
    - 3. Easier to bridge other formats/models
    - 4. Looser coupling
  - How
    - 1. RDF message semantics
    - 2. REST-based SPARQL endpoints
    - 3. XML with GRDDL transformations
    - 4. Aggregators
- PART 2: POC: A SPARQL adaptor for UCMDB
  - What is UCMDB
  - SPARQL adaptor

### PART O

### The problem

#### Problem 1: Integration complexity

- Multiple producers/consumers need to share data
- Tight coupling hampers independent versioning

#### Problem 2: Babelization

- Proliferation of data models (XML schemas, etc.)
- Parsing issues influence data models
- No consistent semantics
- Data chaos

Tower of Babel, Abel Grimmer (1570-1619)

### PART 1

# RDF: The lingua franca for information exchange

# Why?

Four reasons . . .

#### Why? 1. Focus on semantics

- XML:
  - Schema is focused on how to serialize
    - Constrains more than the model
  - Parent/child and sibling relationships are not named
    - Are their semantics documented? E.g., does sibling order matter?
- RDF:
  - One URI per concept
  - Syntax independent
- Who cares about syntax?

Blue App has model

Red App has model

• Need to integrate Red & Blue models

- Step 1: Merge RDF
- Same nodes (URIs) join automatically

- Step 2: Add relationships and rules
- (Relationships are also RDF)

#### Why? 3. RDF helps bridge other formats/models

- Producers and consumers may use different formats/models
- Rules can specify transformations
- Inference engine finds path to desired result model

#### Why? 4. Looser coupling

- Without breaking consumers:
  - Ontologies can be mixed and extended
  - Triples can be added
- Producer & consumer can be versioned more independently

#### Example of looser coupling

- RedCust and GreenCust ontologies added
- Blue app is not affected

# How?

Four ways . . .

#### How? 1. RDF message semantics

- Interface contract specifies RDF, regardless of serialization
- RDF pins the semantics

#### How? 2. REST-based SPARQL endpoints

#### **REST-based SPARQL endpoints**

- Why REST:
  - HTTP is ubiquitous
  - Simpler than SOAP-based Web services (WS\*)
  - Looser process coupling

#### **REST-based SPARQL endpoints**

#### • Why SPARQL:

- One endpoint supports multiple data needs
  - Each consumer gets what it wants
- Insulates consumers from internal model changes
  - Inferencing transforms data to consumer's desired model
  - Looser <u>data</u> coupling

#### How? 3. XML with GRDDL transformations

#### GRDDL is a W3C standard

GRDDL permits RDF to be "gleaned" from XML

- XML document or schema specifies desired GRDDL transformation
- GRDDL transformation produces RDF from XML document
- Mostly intended for getting microformat and other data/metadata from HTML pages

# Using GRDDL for XML document semantics

- Each XML format can be viewed as a <u>custom serialization</u> of RDF!
  - GRDDL transformation produces semantics of the XML document
- Helps bridge XML and RDF worlds
- Same XML document can be consumed by:
  - Legacy XML app
  - RDF app
- App interface contract can specify RDF
  - Serializations can vary
  - Semantics are pinned by RDF

# Using GRDDL for XML document semantics

See: http://dbooth.org/2007/rdf-and-soa/rdf-and-soa-paper.htm

#### How? 4. Aggregators

- Gets data from multiple sources
- Provides data to consumers

#### Aggregator

- Conceptual component
  - Not necessarily a separate physical service
- Handles mechanics of getting data
  - Different adaptors for different sources
    - REST, WS\*, Relational, XML, etc.
    - Diverse data models
  - Might do caching and query distribution (federation)
- Provides model transformation
  - Plug in ontologies and inference rules as needed

### PART 2

# Proof-of-Concept: A SPARQL adaptor for UCMDB

#### IT Service Management (ITSM)

- Manage IT environment
- Configuration Management Data Base (CMDB) is central

#### The HP Universal CMDB (UCMDB)

Goal:

 Maintain a comprehensive and current record of all configuration items (CIs) and their relationships

#### CMDB : Configuration Management DB

#### Example: host information

#### SPARQL adaptor

- Uses existing SOAP interface to UCMDB
- Enables SPARQL queries
- Results can be RDF
- No model transformation (yet)

#### Architecture of SPARQL adaptor

#### UCMDB ontology

 The HP UCMDB ontology defines CI types and relationship hierarchies.

Derived automatically from HP UCMDB metadata.

#### Jena based implementation

#### • Jena, ARQ, Joseki developed at HP Labs\*.

Jena : Semantic Web toolkit

ARQ : Query Engine

Joseki : SPARQL server

RDF, OWL, inference

SPARQL query algebra, evaluation

SPARQL protocol

\* http://www.hpl.hp.com/semweb/

#### Query returning a table

Select the names of host servers on the network with addresses from 192.168.81.0

```
SELECT ?host_name
WHERE {
  [ a object:network ] attr:network_netaddr "192.168.81.0" ;
  link:member [ a object:host ;
    attr:host_dnsname ?host_name
] }
```

#### host\_name

"ILDTRD129" ^^<http://www.w3.org/2001/XMLSchema#string>

"JONI" ^^<http://www.w3.org/2001/XMLSchema#string>

"MBADIR-IL" ^^<http://www.w3.org/2001/XMLSchema#string>

#### Query returning an RDF subgraph

🙆 RDFScope
source results
Edit
PREFIX object: <http: cmdb.mercury.com="" object#=""></http:>
PREFIX link: <http: cmdb.mercury.com="" link#=""></http:>
PREFIX attr: <http: attribute#="" cmdb.mercury.com=""></http:>
PREFIXixs: <a href="http://www.w3.org/2001/XMLSchema#&gt;">&gt;</a>
DESCRIBE ?network ?host ?database WHERE { ?network a object:network; attr:network_netaddr "192.168.81.0"; link:member ?host. ?host a object:nt; link:container_f ?database.
Bescribe a network
(100.1(0.01.0) with bost
(192.168.81.0) WITH HOST
servers containing a DB.

#### Example RDF result set

#### Outline

- PART O: The problem
- PART 1: RDF: The lingua franca for information exchange
  - Why
    - 1. Focus on semantics
    - 2. Easier data integration
